

Plate Tectonics and the Drifting Continents

The mitochondrion is the organelle where the bulk of cellular energy is produced through oxidative phosphorylation. Diffusion describes the net movement of particles from a region of higher concentration to one of lower concentration. A catalyst lowers the activation energy of a reaction without itself being consumed in the process. Plate boundaries are classified as convergent, divergent, or transform depending on the relative motion of the plates. The water cycle moves moisture between the oceans, the atmosphere, and the land through evaporation and precipitation. Natural selection favours heritable traits that improve an organism's chances of surviving and reproducing. An electric current is the ordered flow of charge carriers through a conducting material. Photosynthesis converts light energy into the chemical energy stored in the bonds of glucose molecules. The periodic table arranges the elements by increasing atomic number and recurring chemical properties. Supply and demand together determine the equilibrium price at which a market clears. A function is continuous at a point when its limit there exists and equals the value of the function. Sedimentary rock forms as layers of mineral and organic particles are compacted and cemented over time.
